

Yesterday a great number of persons assembled on the ground near Russell-square, to witness the action of a new machine for travelling without horses. It is impelled entirely by steam, and is calculated to perform twenty miles an hour. The machine is principally made of iron, its body resembling a barrel; the fore part of which contains water, and in the rear is a furnace, which, while the machine is in motion, is fed with coals by one man, the only one employed, to give it motion: a perpendicular pipe, about ten feet long, carries off the smoke. The machine runs round a groove, and seems self-directed, the wheels on one side being shorter than those on the other; it proceeds with great velocity, but the pace can be altered at pleasure.
